## **Cancure: The Cancer Care Environment**

### **The Problem**

Cancer care in India is fragmented at every step.

A patient may consult multiple hospitals, multiple specialists, diagnostic centers, and pharmacies across the course of treatment. Reports live in paper files, PDFs, WhatsApp forwards, discharge summaries, and incompatible hospital systems. There is no single place that holds the full journey.

This fragmentation shifts the real burden onto the caregiver, who becomes the human EMR. They chase reports, manage appointments, track medicines, repeat the patient's history at every new consultation, and try to prevent mistakes in emergencies. The result is lost time, missed follow-ups, delayed refills, repeated tests, confusion across providers, and unnecessary stress for families already under pressure.

The core issue is not that cancer care lacks tools. The issue is that care is scattered across too many disconnected tools.

### **The Gap**

Existing solutions solve only one part of the problem.

Hospital EMRs are institution-centric and usually not accessible across providers. Personal health record apps mostly store data passively; they do not actively coordinate care. Oncology AI platforms are often built for research or enterprise use, not for patients and families managing day-to-day treatment. Adherence apps focus on reminders, but not on the full treatment journey. Telemedicine adds another channel, but not a unified care environment.

What is missing is not another app. What is missing is an environment where patients, caregivers, doctors, hospitals, and pharmacists can work together without friction, while each still keeps their own role and access level. A system that does not force hospitals to replace their existing workflows, but still connects the journey around the patient.

### **Our Solution**

Cancure is a secure, role-based cancer care environment.

# CANCURE

Every participant in the journey gets their own portal, but all of them connect through a shared, patient-controlled data layer. The patient and caregiver hold the single source of truth. Doctors can view a structured summary instead of chasing scattered documents. Hospitals can access emergency and admission information faster. Pharmacists can confirm prescriptions and mark dispensing. Admins can manage accounts, access, audit logs, and compliance.

Cancure is designed to keep care coordination inside one environment instead of pushing people back into WhatsApp, paper files, and fragmented communication.

## Key Features

Cancure is built around the real coordination problems in cancer care.

### Medical Vault + OCR

Users can upload any report, prescription, blood test, pathology file, or imaging summary. AI extracts structured information from these documents and stores it in a usable format.

### Doctor-Ready Brief

Cancure can generate a one-page structured summary of the patient's complete journey on demand. This helps doctors understand the case quickly without asking the family to repeat everything from memory.

### Medication Continuity Engine

Every prescription is tracked. The system sends escalating reminders as medicines run low, supports adherence confirmation, and helps families avoid gaps in treatment.

### Connect inside the environment

Patients and caregivers can search for doctors, hospitals, or pharmacists inside Cancure and request record sharing directly. No dependence on external links, scattered chats, or manual forwarding.

### Emergency Auto-Send

In urgent situations, one tap can send the patient's brief, location, and navigation context to the nearest oncology hospital's emergency dashboard, along with two-way communication support.

### What's Missing? Intelligence

Cancure can flag overdue blood tests, missing imaging, incomplete treatment courses, and follow-up gaps so families can act before problems escalate.

## Why We Are Different

# CANCURE

Most competitors solve a narrow slice of the workflow. Cancure is built as the coordination layer itself.

Hospital EMRs are usually locked inside one institution. Cancure is patient-controlled and works across providers. Personal health record apps are mostly storage. Cancure is active coordination. Adherence apps focus on reminders only. Cancure tracks the full continuity of care. Telemedicine handles consultations. Cancure handles the system around the consultation. Oncology AI tools are usually aimed at research or enterprise analytics. Cancure is built for patients, caregivers, doctors, hospitals, and pharmacists working together in real life.

The biggest difference is structural: Cancure is not just a feature set. It is an environment.

That gives it a stronger network effect. Once a family's records, medication history, and care coordination live inside the platform, the system becomes harder to replace. The value rises as more participants join, because every new doctor, hospital, or pharmacist improves the utility of the same shared environment.

## **Why People Should Trust Cancure**

Cancure is designed for India, not imported assumptions.

It is being built around real workflows observed through conversations with caregivers, doctors, and hospital administrators. The platform is shaped by how cancer care actually works in India: multi-provider, paper-heavy, family-driven, and coordination-intense.

Trust also comes from the product boundaries. Cancure does not diagnose, stage, or recommend treatment. It organizes, tracks, and coordinates. That keeps the platform focused on solving the operational pain without overreaching into clinical decision-making.

Privacy and security are central. Cancure uses role-based access, audit logs, and encrypted storage. The patient or caregiver controls what gets shared and with whom. The patient data is not sold.

The environment is built to reduce confusion, not create it. One login. One shared data layer. One coordination system for the cancer journey.

## **Closing**

Cancure exists because cancer care fails when information is fragmented.
